# The optprob package\*

#### Yudai NAKATA

July 29, 2016

#### Abstract

<code>optprob</code> is a package that offers you useful features for writing optimization problems in a structured manner. The package also provides highly customizable options for the appearance of the optimization problems.

# 1 Introduction

#### 1.1 Motivation

In order to illustrate optimization problems, one can utilize alignat environment from the amsmath package. A simple example like this,

```
\documentclass{article}
\usepakcge{amsmath}
\DeclareMathOperator*\maximize{maximize}
\begin{document}
   \begin{alignat}{2}
        & \mathord{\maximize_{x_1,x_2\in\mathbf{R}}} & \quad & c_1x_1+c_2x_2 \\
        & \text{subject to} & & a_{11}\x_1+a_{12}\x_2 \leq b_1 \\
        & & & a_{21}\x_1+a_{22}\x_2 \leq b_2.
   \end{alignat}
\end{document}
```

<sup>\*</sup>https://github.com/yudai-nkt/optprob

will produce

$$\underset{x_1, x_2 \in \mathbf{R}}{\text{maximize}} \quad c_1 x_1 + c_2 x_2 \tag{1}$$

subject to 
$$a_{11}x_1 + a_{12}x_2 \le b_1$$
 (2)

$$a_{21}x_1 + a_{22}x_2 \le b_2. (3)$$

One can also use other align-variant environments or array environment.

Each method has its pros and cons, but none of them are very friendly when it comes to denoting optimization problem. Writing disgusting numbers of ampersands in every line for the proper alignment is really annoying (to me at least) and could sometimes look ugly if we only input inadequate ampersands. Also, it is difficult to intuitively grasp the role of each formulae at a glance upon the source code if we put them manually.

### 1.2 Objective of this package

The optprob package provides an elegant and semantic syntax for optimization problems. With the aid of this package, you are free from the concern about the number of ampersands. You can easily switch the spacing or other settings via  $\langle key \rangle = \langle value \rangle$  syntax. Semantically-named macros enhance your code's readability compared to the bare LATEX expression.

# 2 Requirements

The optprob package is supported on the following engines and format.

- TEX engine: TEX, pdfTEX, XTEX, LuaTEX, pTEX and upTEX
- TEX format: LATEX  $2\varepsilon$  (plain TEX and ConTeXt are not supported.)

This package requires mathtools and pgfkeys to make use of it, and listed below are necessary packages to typeset this documentation besides the prerequisite packages:

• fontenc • lmodern • multicol

• geometry • ltxdockit

hologominted

All the packages above are bundled with recent TEX Live by default. If any of them are not installed in your TEX system, you can download them via CTAN.

### 3 Installation

Clone the repository or download from the Releases. It includes three files, i.e. optprob.pdf, optprob.sty and optprob.tex. Following TDS (TEX Directory Structure), move each file to the corresponding directories as follows:

- optprob.pdf and optprob.tex  $\rightarrow$  texmf/doc/latex/optprob/
- $\bullet \ \ \, {\tt optprob.sty} \to {\tt texmf/tex/latex/optprob/},$

where texmf is either \$TEXMFLOCAL or \$TEXMFHOME. Make sure to run mktexlsr if necessary.

# 4 Usage

#### 4.1 Package loading

Just put this line in your preamble:

\usepackage{optprob}

For the time being, this package has no options available.

#### 4.2 Macros and environments

#### \argmax

prints "arg max", which denotes arguments of the maximum.

#### \argmin

is the minimum counterpart of \argmax.

 $\verb|\begin{optimize}| [\langle layout\ formatting \rangle] {| \langle operation\ type \rangle}| \\$ 

#### \end{optimize}

either max or min can be used for  $\langle operation\ type \rangle$  according to the problem you want to represent. You can specify the design of the environment in the  $\langle layout\ formatting \rangle$  option. Each setting can be given in  $\langle key \rangle = \langle value \rangle$  syntax as follows.

abbrev=true, false default: false

to or not to abbreviate the terms such as maximize, minimize and subject to.

showeqnum=true, false default: true

to or not to show the equation numbers in each line.

 $\mathtt{space} = \langle \mathit{dimension} \rangle$  default: 1em

space between two columns.

 $\lceil \lceil \lceil \rceil \rceil \rceil$ 

\end{maximize}

is equivalent to the optimize environment with the mandatory argument set to max.

 $\begin{minimize} [\langle layout\ formatting \rangle] \end{minimize}$ 

\end{minimize}

is equivalent to the optimize environment with the mandatory argument set to min. Note that this and maximize environments are defined only if \minimize and \maximize are not defined in the preamble respectively.

Within these environments above, the following macros are locally defined:

 $\oldsymbol{\label{localization} \oldsymbol{\localization} \label{localization} \label{localization} $$\operatorname{\localization} \ (\oldsymbol{\localization} \) $$ \coldsymbol{\localization} \) $$\coldsymbol{\localization} \) $\coldsymbol{\localization} \) $\$ 

sets the objective function to be maximized or minimized and denotes the variables over which the objective function is optimized. The default value for optional argument is an empty string. You must use this macro once per one environment.

### $\addconstraint{\langle constraint \rangle}$

adds constraints of the problem. You can use this macro as many times as necessary.

# 4.3 Demos

I will demonstrate some simple examples.

```
\begin{optimize}{max}
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           maximize
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    2x-y
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          (4)

# 7 Changelog

```
v0.2.0 (July 5, 2016)
```

- Add an option for switching the appearance of equation numbers.
- Change the way of specifying variables in optimize environment and friends.

```
v0.1.1 (July 5, 2016)
```

• Fix the incompatibility with minipage environment.

```
v0.1.0 (May 25, 2016)
```

• First publication.
